6. The  $\overline{RESET}$  pin must tolerate high voltages when entering and operating in programming modes and, as a consequence, has a weak drive strength as compared to regular I/O pins. See [Figure 3-19](#), [Figure 3-20](#), [Figure 3-21](#), and [Figure 3-22](#) (starting on [page 18](#)).

8. Brown-Out Detection (BOD) disabled.

## 2.2 Clock Characteristics

### 2.2.1 Calibrated Internal RC Oscillator Accuracy

It is possible to manually calibrate the internal oscillator to be more accurate than default factory calibration. Please note that the oscillator frequency depends on temperature and voltage. Voltage and temperature characteristics can be found in [Figure 3-36 on page 27](#) and [Figure 3-37 on page 27](#).

**Table 2-2.** Calibration Accuracy of Internal RC Oscillator

Calibration Method	Target Frequency	$V_{CC}$	Temperature	Accuracy at given Voltage & Temperature <sup>(1)</sup>
Factory Calibration	8.0 MHz <sup>(2)</sup>	3V	25°C	±10%
User Calibration	Fixed frequency within: 6 – 8 MHz	Fixed voltage within: 1.8V - 5.5V <sup>(3)</sup> 2.7V - 5.5V <sup>(4)</sup>	Fixed temperature within: -40°C to +125°C	±1%

- Notes:

## 2.3 System and Reset Characteristics

### 2.3.1 Power-On Reset

**Table 2-3.** Characteristics of Power-On Reset.  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$

Symbol	Parameter	Min <sup>(1)</sup>	Typ <sup>(1)</sup>	Max <sup>(1)</sup>	Units
$V_{POR}$	Release threshold of power-on reset <sup>(2)</sup>	1.1	1.4	1.7	V
$V_{POA}$	Activation threshold of power-on reset <sup>(3)</sup>	0.6	1.3	1.7	V
$SR_{ON}$	Power-On Slope Rate	0.01			V/ms

- Note:
1. Values are guidelines, only
  2. Threshold where device is released from reset when voltage is rising
  3. The Power-on Reset will not work unless the supply voltage has been below  $V_{POT}$  (falling)

## 2.4 Brown-Out Detection

**Table 2-4.** BODLEVEL Fuse Coding.  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$

BODLEVEL[2:0] Fuses	Min <sup>(1)</sup>	Typ <sup>(1)</sup>	Max <sup>(1)</sup>	Units
111	BOD Disabled

101	2.5	2.7	2.9	
100	4.1	4.3	4.5	
0XX	Reserved			

Note: 1.  $V_{\text{BOT}}$  may be below nominal minimum operating voltage for some devices. For devices where this is the case, the device is tested down to  $V_{\text{CC}} = V_{\text{BOT}}$  during the production test. This guarantees that a Brown-out Reset will occur before  $V_{\text{CC}}$  drops to a voltage where correct operation of the microcontroller is no longer guaranteed.

### 3. Typical Characteristics

The data contained in this section is largely based on simulations and characterization of similar devices in the same process and design methods. Thus, the data should be treated as indications of how the part will behave.

The following charts show typical behavior. These figures are not tested during manufacturing. All current consumption measurements are performed with all I/O pins configured as inputs and with internal pull-ups enabled. A sine wave generator with rail-to-rail output is used as clock source.

The power consumption in Power-down mode is independent of clock selection.

The current consumption is a function of several factors such as: operating voltage, operating frequency, loading of I/O pins, switching rate of I/O pins, code executed and ambient temperature. The dominating factors are operating voltage and frequency.

The current drawn from capacitive loaded pins may be estimated (for one pin) as  $C_L \cdot V_{CC} \cdot f$  where  $C_L$  = load capacitance,  $V_{CC}$  = operating voltage and  $f$  = average switching frequency of I/O pin.

The parts are characterized at frequencies higher than test limits. Parts are not guaranteed to function properly at frequencies higher than the ordering code indicates.

The difference between current consumption in Power-down mode with Watchdog Timer enabled and Power-down mode with Watchdog Timer disabled represents the differential current drawn by the Watchdog Timer.
